Motivation

□ Key question

- How to build an **economically efficient** and **technically feasible market place** for users to trade goods or services over the Internet?

□ Economic approach

- Use of **auctions**
 - Well established concept
 - Economically efficient (=> maximal benefits)

□ Key technical requirements

- **Scalability** (=> scale to any number of users)
- **Reliability** (=> correctness, continuous availability, security)
- **Technical efficiency** (=> efficient use of resources, i.e. CPU, storage, network links)

Centralized versus Decentralized Auctions

□ Centralized (C/S) auctions

- Dedicated (centralized) broker (e.g. eBay)
- + High reliability
- + High technical efficiency
- Single Point of Failure
- Vulnerable against attacks
- Not scalable

□ Decentralized (P2P) auctions

- Peers act as brokers, providers, and consumers **at the same time**
- + No Single Point of Failure
- + Scalable
- Vulnerable against selfish or malicious peers
- Technical feasibility?

Goals and Outline

□ Goals

- Maintain the **economic efficiency** of auctions
- Exploit the **scalability** and **resilience** of P2P networks
- Achieve a **high reliability** even in the presence of **malicious** peers
- Provide a **technically efficient** solution

=> Focus on **technical feasibility** of implementing a P2P auction

□ Outline

- PeerMart's approach and technical design
- Analytical and experimental results

PeerMart Approach

□ Key Idea

- Distributed double auctions
- **Provider** and **consumer** peers offer prices for services
- Offers are **optimally matched** by peers acting as **brokers** for a service

□ Basic Algorithm

- Providers **publish services** they wish to provide
 - Broker peers reply **bid price** (current highest pay price)
- Consumers **request services** they wish to use
 - Broker peers reply **ask price** (current lowest sell price)
- Brokers run the following **matching strategy** at regular intervals:
 - Upon every price offer, if offer is higher (lower) than current bid price (ask price) => no match, store offer in a table
 - Otherwise, forward offer to the peer with the best counteroffer (highest bid / lowest ask)

Technical Design

- PeerMart uses a **structured P2P overlay network** to distribute broker load
 - **Pastry** is used as underlying infrastructure
 - Provides unique **128-bit nodeIDs**
 - Stores n closest nodeIDs (**leaf-set**) in routing table
- Each peer has a **public / private key pair** to sign messages
 - Assumption: Public keys certified offline by trusted entity and bound to nodeIDs
- Services are mapped onto a **redundant set of n broker peers** (broker-set)
 - Assumption: Services have **unique IDs** (e.g. hash value of a file)

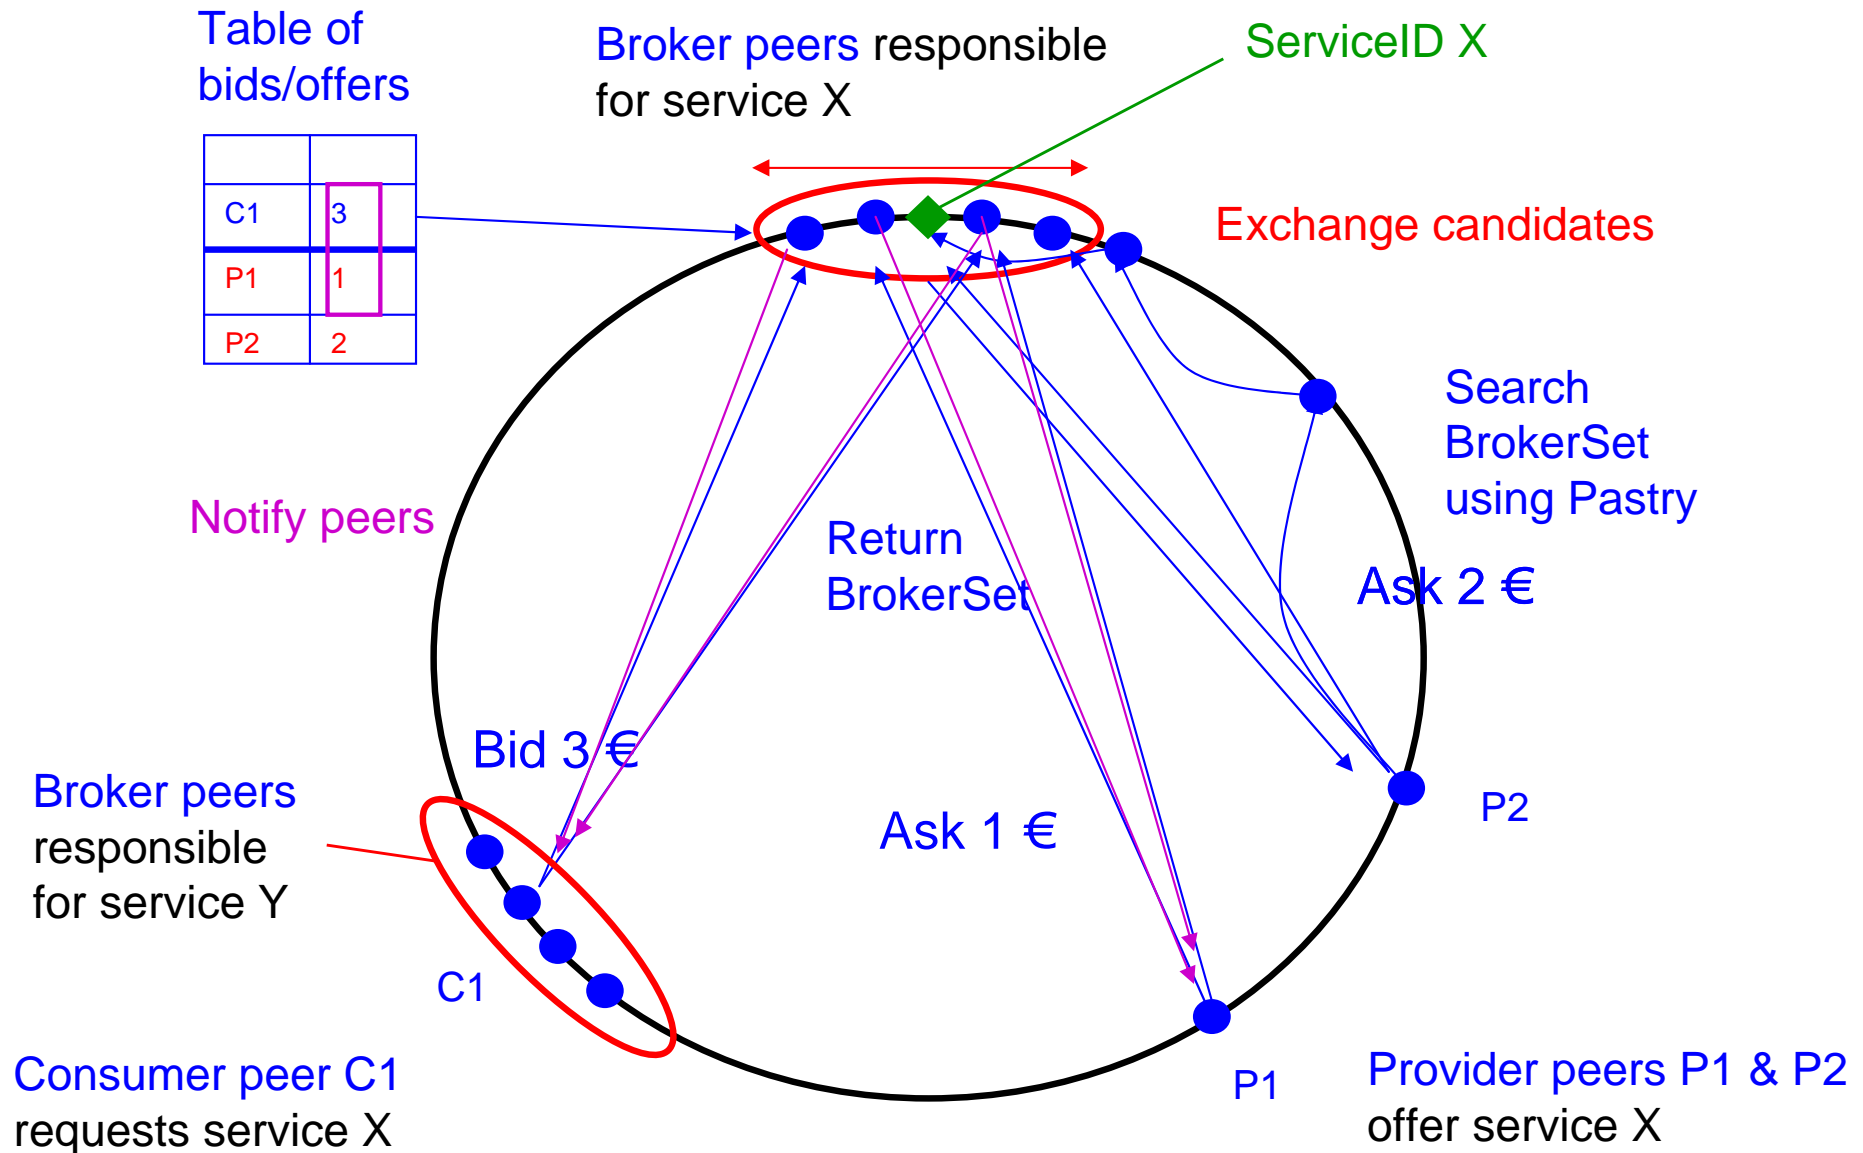

Technical Design (cont'd)

- Consumers/providers **randomly select f** brokers out of the broker set
 - => Load is uniformly distributed on all broker peers
- Each broker peer keeps table of **m highest bids / lowest asks**
 - Lower bids and higher asks are **rejected**
- **Matching** is performed in a **decentralized way**
 - Candidates for a match are **forwarded** to other brokers
 - Candidates: **local matches** and **next best offer**
 - Final matches are determined using **majority decisions**
 - Winners are notified by the f brokers that received the offer

Double Auction in PeerMart

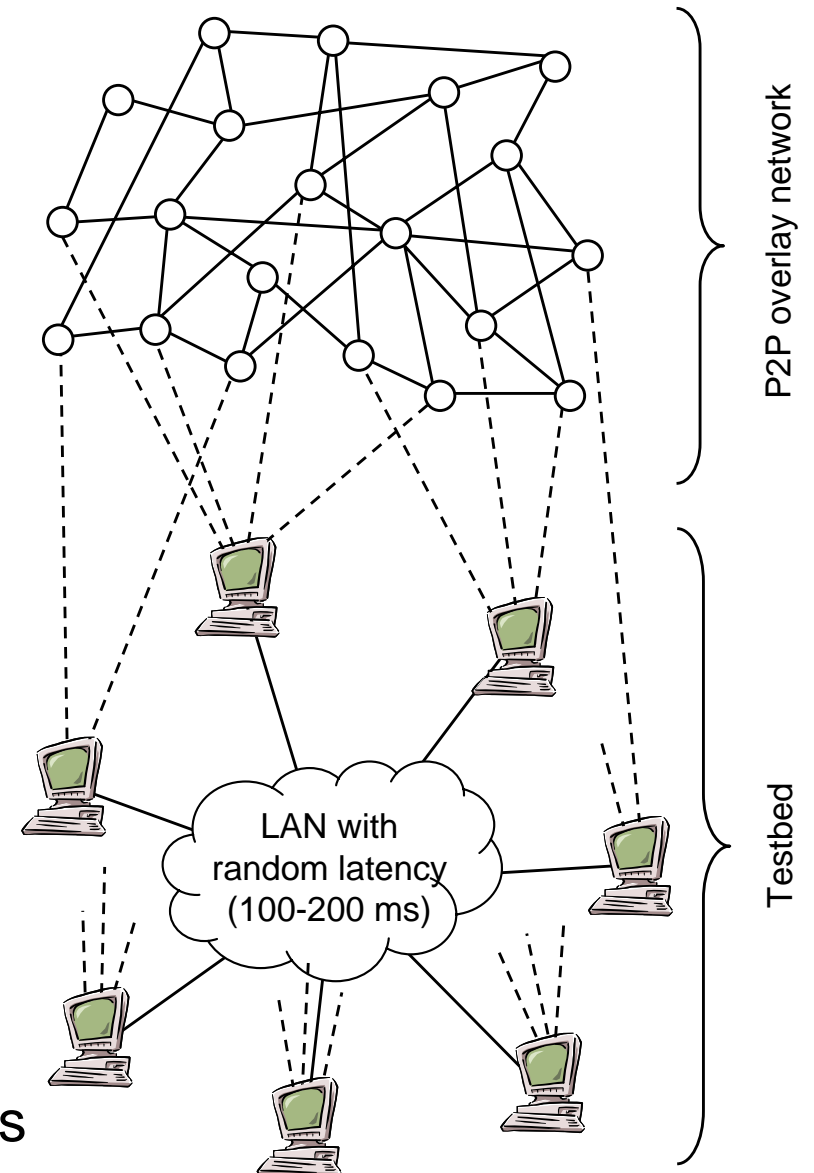

Analytical Results

- Basic effort for **maintaining Pastry** is $O(\log_b N)$
 - N: Number of peers in the network
 - **Finding** responsible **broker-set** is $O(\log_b N)$
 - All subsequent communication is **direct**
 - **Sending offers** is $O(f)$
 - **Exchange/forward** of matching **candidates** is $O(f*n)$
 - **Notify peers** about **final matches** is $O(f)$
 - f: Number of parallel brokers used
 - n: Number of peers in a broker set
 - Avg. number of **offers stored** per peer: $s*n*m$
 - s: Avg. number of service involvements per peer (naturally limited)
 - m: Table size for storing offers (limited)
- } Total costs

Experiment Setup

- Prototype implemented in Java on top of **FreePastry**
- Assumptions for experiments:
 - Each peer assigned to $s = 2$ services
 - Peers follow the ZIP **bidding strategy**
 - Consumer's price offer:
$$p_{bid} = \min(p_{ask} + \alpha(p_{max} - p_{ask}), p_{max})$$
 - Provider's price offer:
$$p_{ask} = \max(p_{bid} - \alpha(p_{bid} - p_{min}), p_{min})$$
 - p_{max} , p_{min} are reservation prices
=> normally distributed such that 50% of offers match, α set to 0.1
 - **Malicious** peers
 - Uniformly distributed
 - Do not forward offers nor notify peers

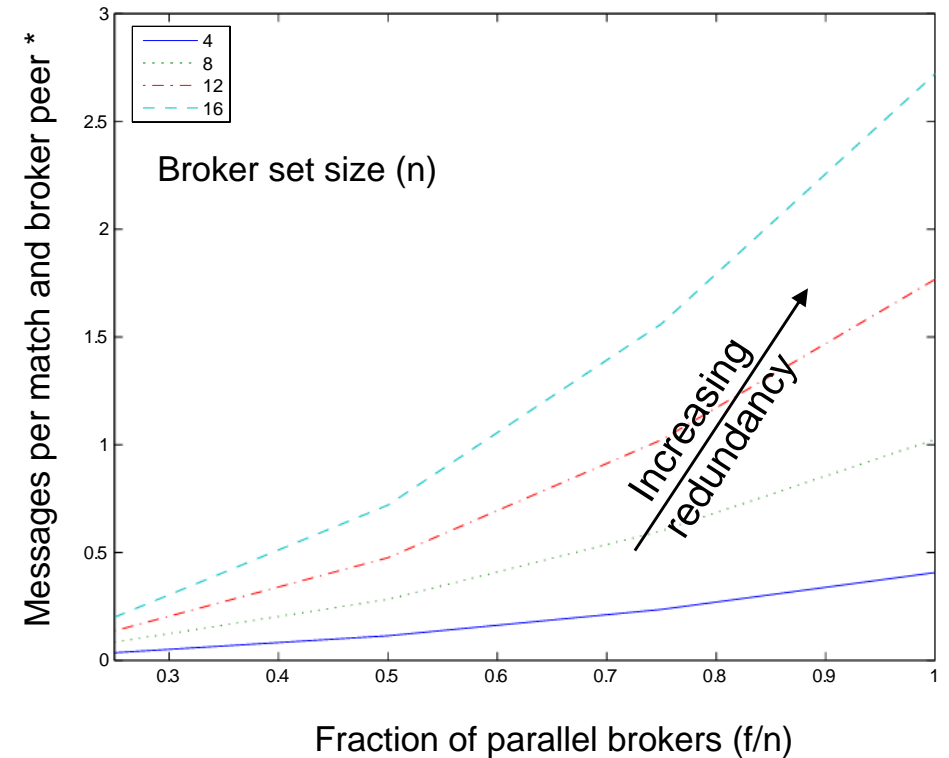

Experimental Results

Scalability

Efficiency (redundancy costs)

Measured security overhead:

- Overhead for SHA1 with DSA signature is ~15% of message size
- Signing / verifying messages takes 10 - 20 ms (~10% of the average RTT) on Pentium 4 CPU 2.4 GHz, 512 MB RAM, Java VM 1.4.2

* Message size is ~1 kB

Experimental Results (cont'd)

- PeerMart correctly matches offer pairs for < 50% malicious peers using, e.g., 8 brokers in parallel (out of 64 brokers in total)

- If fraction of malicious peers is < 25%, even 4 parallel brokers provide good reliability

Conclusions and Future Work

- PeerMart is a **fully distributed auction-based market**
 - Can be used by peers to trade **any services**
- Technically designed on top of a **P2P overlay network**
 - Implemented prototype uses **FreePastry** as underlying infrastructure
- PeerMart is both **technically** and **economically efficient**
 - **Scales** well even for a large number of peers trading services
- **High reliability** even in the presence of **malicious** peers
 - Achieved through redundancy
- **Future Work**
 - Punish peers that do not stay to an offered price (=> use **Reputation**)
 - Study other forms of malicious attacks (e.g. **DDoS**)
 - Consider and prevent **overlay splitting**
 - Run prototype in a real-world environment (e.g. **PlanetLab**)

Thank you! – Any Questions?

P2P Market Model: Roles and Interactions

Consumer's goal:

- Find provider offering a particular service

Provider's goal:

- Find consumer willing to use offered service

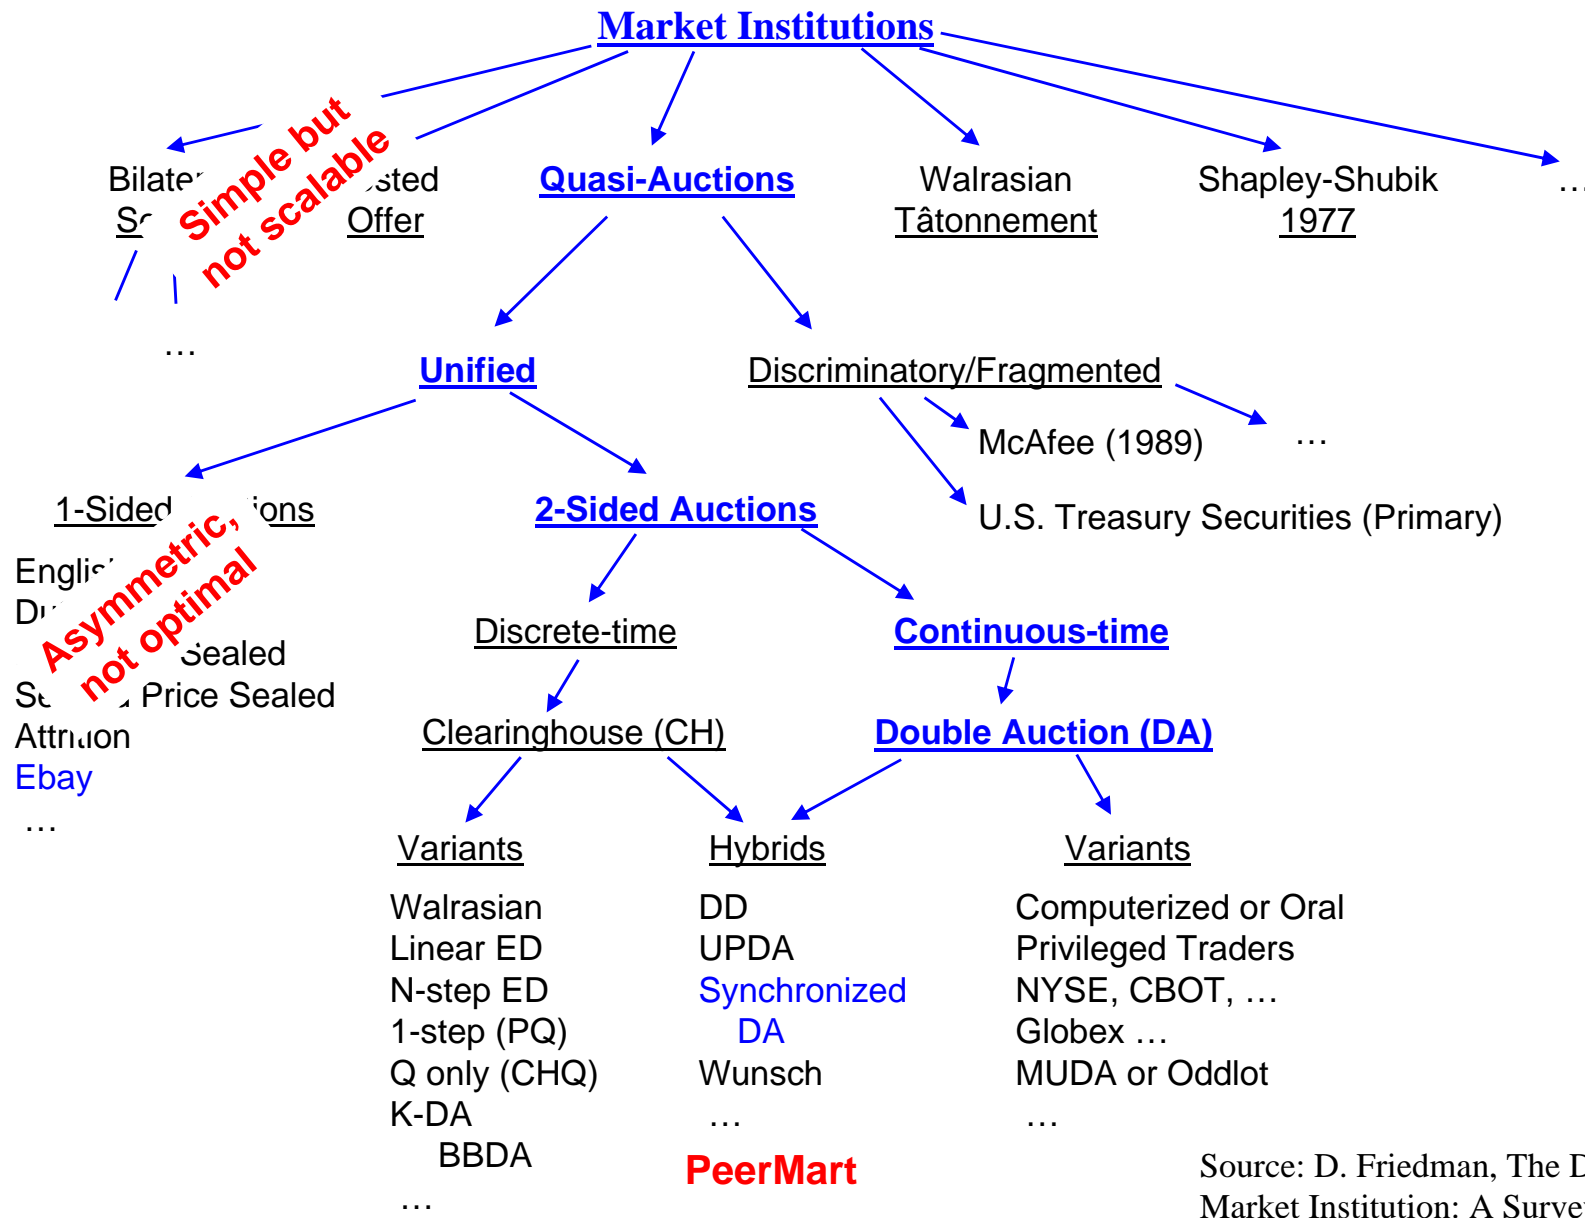

Decentralized Auctions: Main Problems

- Why should peers **cooperate**?
 - **Forwarding** messages (requests / bids / offers etc.)
 - **Caching / Processing** data on behalf of other peers
- Cooperation is **costly**
 - Peers have simply **no incentives** to cooperate
- Even worse: Peers might be **competitors**
 - **Provider peers** could lose opportunity to **sell**
 - **Consumer peers** could lose opportunity to **buy**
- Peers are **autonomous**
 - They may act in a **selfish** or **malicious** way
- **Accounting** for forwarding messages etc is **not feasible**
 - Difficult to measure, high technical effort

Implementation of PeerMart

Exchange Candidates

□ Problem

- Message delay between peers
- Time is not synchronized

=> Introduce time slots greater than max Round Trip Time

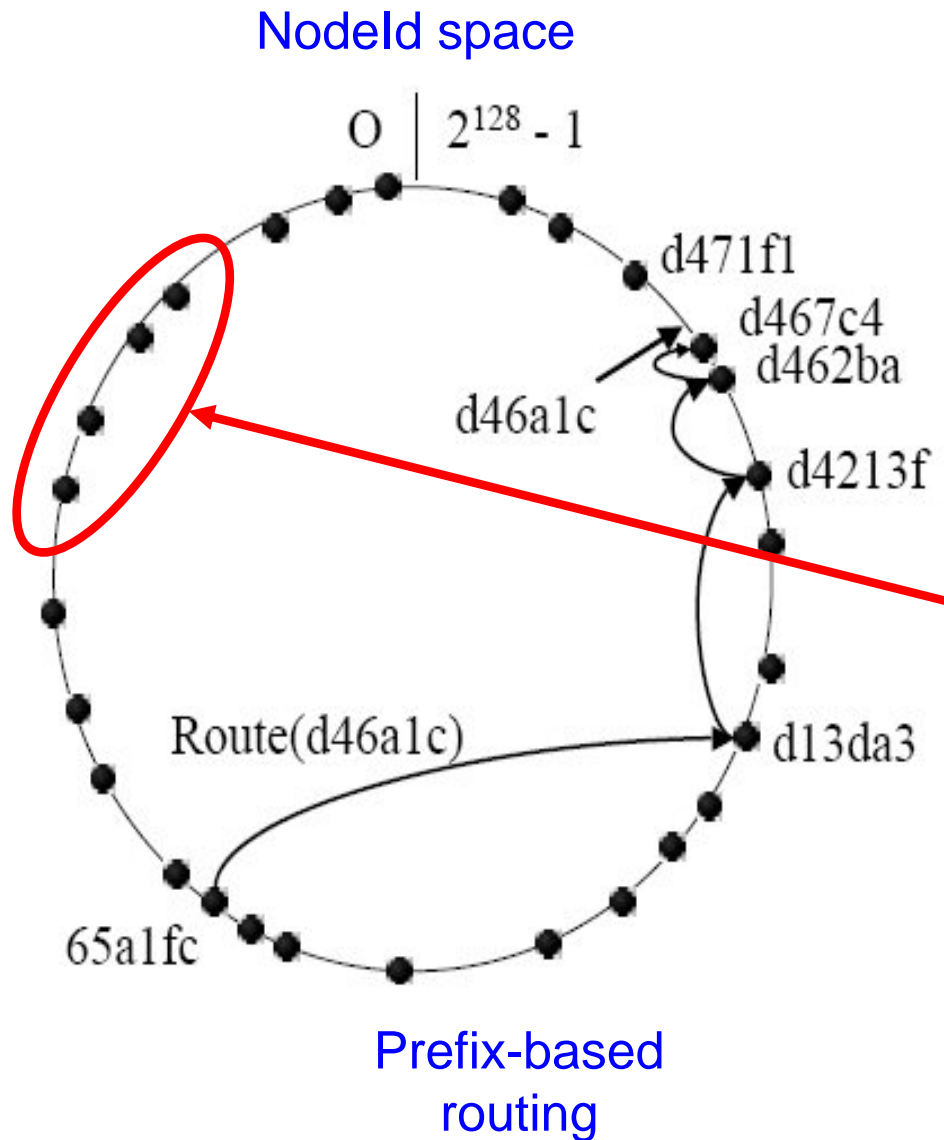

Related Work on P2P Auctions

- Z. Despotovic, J. Usunier, K. Aberer: [Towards Peer-To-Peer Double Auctioning](#); In Proceedings of the 37th HICSS Conference, January 2004.
 - Offers/Bids are broadcasted in a Gnutella-like fashion
 - Any peer can answer with a counteroffer
 - Not scalable, not strategy-proof
- E. Ogston, S. Vassiliadis: [A Peer-to-Peer Agent Auction](#); In Proceedings of AAMAS Conference, July 2002.
 - Agents are connected in a random network
 - Single agent is assigned as cluster center
 - Cluster size is limited => not scalable
 - No message delay is assumed => not realistic
- M. Fontoura, M. Ionesu, N. Minsky: [Decentralized Peer-to-Peer Auctions](#); Journal of Electronic Commerce Research, January 2005.
 - Based on Law Governed Interaction (LGI) paradigm
 - Only the auction process itself is decentralized
 - Communication overhead due to routing messages via controllers
- Many more on double auctions (not P2P) ...

Underlying Infrastructure: Pastry

Unique 128-bit **nodelds** (calculated from a peers IP address or public key using secure hash function)

Open source implementation (**FreePastry**)
